

The Ecosystem Disturbance and Recovery Tracker (eDaRT)

system prototype or high-fidelity near-real time ecosystem monitoring

1. Introduction

Across the globe, the demand for timely and accurate ecosystem dynamics information at the Landsat spatial scale and various temporal scales is growing, and as of today, still exceeds the product availability. The diversity of disturbance metrics, sensitivity vs. reliability trade-offs, as well as requirements from timeliness of product generation and needed customizations, suggest that a single "centralized" comprehensive system is not likely to fill such diverse and dynamic demand in the near future.

To address daily ecosystem management needs, we have developed an initial version of the *Ecosystem Disturbance and* Recovery Tracker (eDaRT) system prototype for rapid product generation beyond annual assessment and comparisons to take advantage of all available Landsat images.

2. eDaRT Objectives

- ➤ Address multiple questions & inform land management: Early detection (accurate timing) of disturbances for rapid assessments and tactical decision making;
- **Sensitivity** to low-magnitude & small scale effects;
- Reliability & Robustness against phenological and other irrelevant variability (not simply changes, but anomalies!)
- **Grasslands and Shrublands, too** (not only forests!)
- **Customized** Product Development and **Rapid** generation

3. Features & Current Functionality

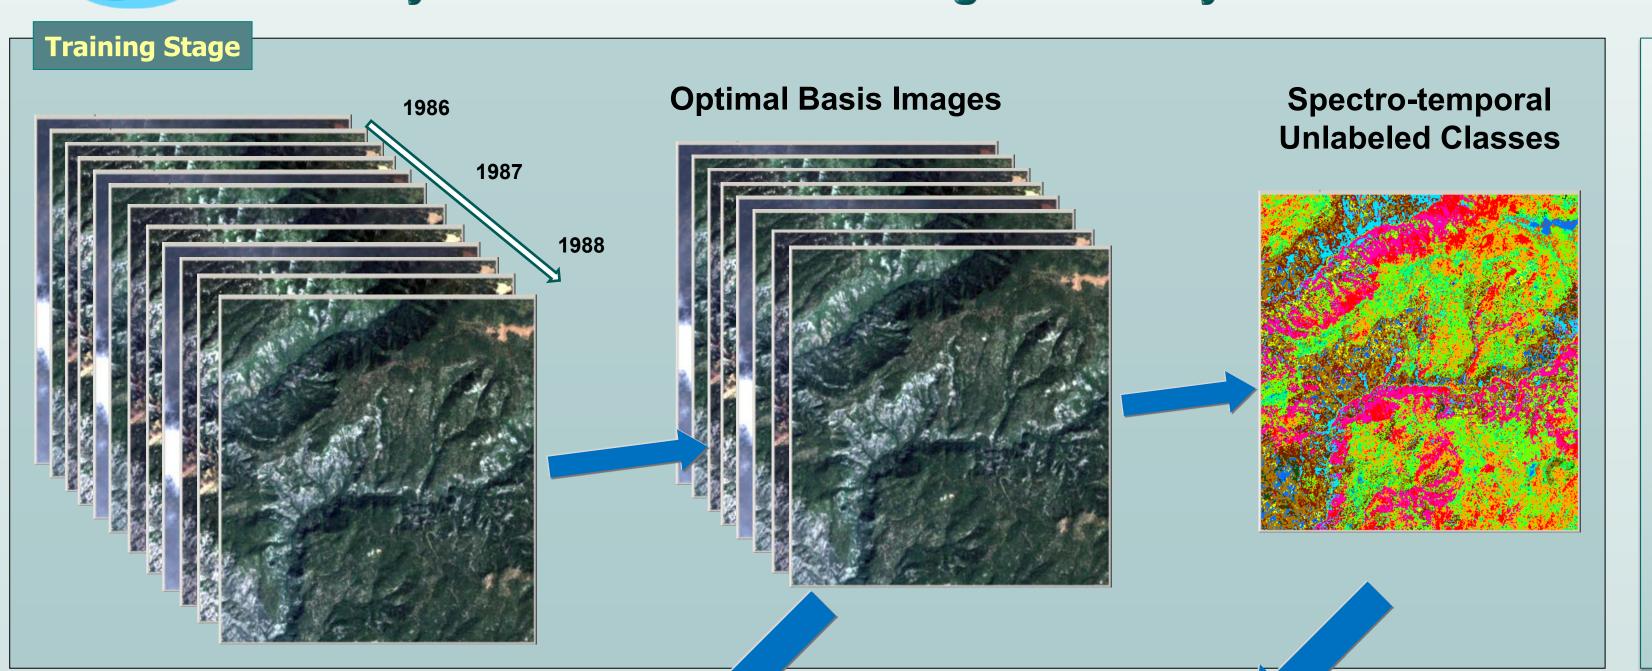

- > Can process all available images.
- currently, Landsat 5/7 with <90% scene cloud/snow area > Fixed, user-defined baseline period. No need to wait until there are enough cloud-free recent observations available:
- > Combines spectral, temporal, and spatial information
- > Currently available products (MATLAB & ENVI formats)
 - Cumulative Effect Classification Maps (for each date): Disturbed (11 confidence classes), (see sect. 5.5)
 - Regenerating (11 confidence classes)

it is "ready to go" with the first available image.

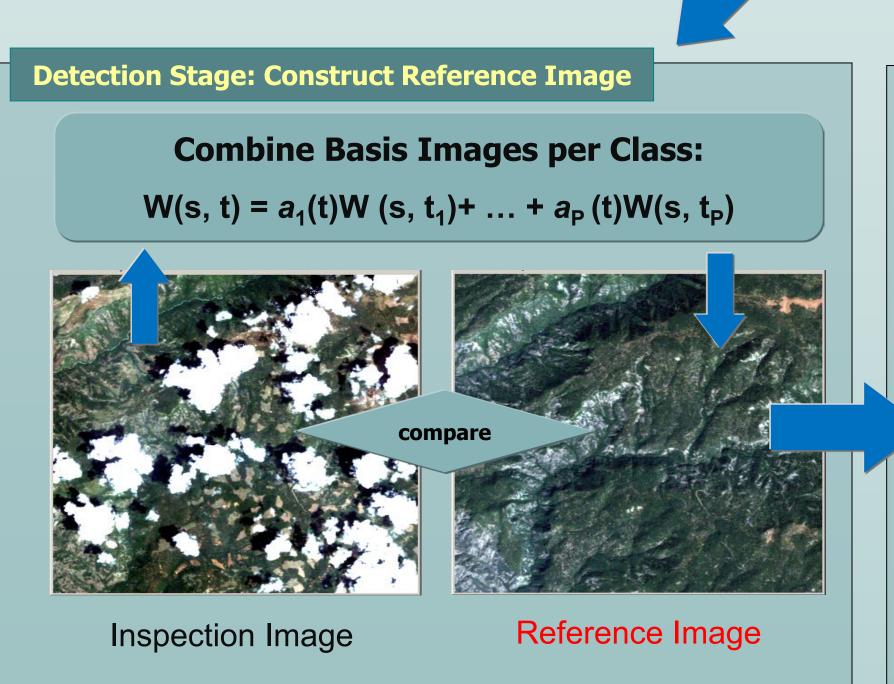

- Timing of the First Disturbance Event (sect. 5.6)
- Temporally filtered maps: retain only repeat detections

4. Algorithm Overview

Anomaly Detection Method: Segmented Dynamic Detection Model (sDDM)

- ➤ The Segmented DDM extends the DDM approach by Koltunov et al. (2009).
- > The sDDM concept: resolve the "no-anomaly" value at a pixel of a current image using:
 - past values at that pixel, and
 - the relationship between past and current values at other pixels belonging to a similar land cover type
- > eDaRT fuses the sDDM with spatial context analysis, thus boosting detection sensitivity.

Coefficients a(t) are estimated by robust regression to represent evolution of undisturbed landscapes
